CC 15-2 (Immunochemistry)

AB The plateau values of 125I-labeled antibody binding by the rabbit immunoadsorbents to bovine serum albumin fragments 377-571 and 504-581 changed with time after the initial immunization, but were, for a given antiserum, identical in all serial antiserums obtained from 15-39 days. In very early antiserums (7 days) the larger fragment (377-571) possessed a higher immunochem. reactivity than the small fragment (504-581). Comparison of the inhibitory activities of the 2 fragments towards the binding of albumin-125I and 125I-labeled fragment 377-571 with serial antiserums to bovine serum albumin in a Farr assay showed that fragments 377-571 and 504-581 exhibited comparable inhibitory activities, and that fragment 504-581 could completely inhibit the binding of the 125I-labeled fragment 377-571. Acid dissociation studies showed that the affinities of serial 125I-labeled antibodies for immunoadsorbents increased, whereas their heterogeneity decreased with time after immunization. Thus, although in very early (7 days) antiserums the larger fragment probably carries some addnl. antigenic sites, the shared antigenic sites become completely

     A solid-phase immunoassay for determining Hb in a human stool sample comprises
     (1) forming a dispersion of 1-10 weight% stool sample in an aqueous fecal test
     solution containing a buffer, a biocide in a concentration for inhibiting
microbial
     growth, and a proteolytic enzyme inhibitor in a concentration sufficient to
     inactivate a major proportion of the proteolytic activity; (2) permitting
     the fecal solids in the dispersion to settle to form a liquid phase
     substantially free from fecal solids; (3) removing the liquid phase; (4)
     contacting the liquid test sample with a solid support to which an
     anti-(human Hb) antibody is adhered for a time sufficient to
     permit antibody conjugation with analyte; and (5) determining analyte
     adhering to the insol. support. Stool samples were dispersed in fecal
     test solution (0.02 M phosphate-buffered saline, pH7.4, containing NaN3 0.1,
     bovine serum albumin 1.0 weight%, aprotinin
     10,000 units/L, and HCHO 694 \muL/L) and the clarified stool sample
     solns. were analyzed by EIA and agglutination immunoassay. The
     immunoassays gave 76% agreement with a com. quaiac paper test.

     A new protein, called alboaggregin-B (AL-B), has been isoalted from
AΒ
     Trimeresurus albolabris venom by ion-exchange chromatography. It
     agglutinated platelets without the need for Ca2+ or any other
                The purified protein showed an apparent molecular mass on
     cofactor.
     SDS-PAGE and gel filtration of about 23 kDa under nonreducing conditions.
     Ristocetin did not alter the binding of AL-B to platelets or affect
     AL-B-induced platelet agglutination. Agglutinating
     activity was not dependent on either proteolytic or lectin-like activity
     in AL-B. Binding analysis showed that AL-B bound to platelets with high
     affinity (Kd = 13.6 \pm 9.3 nM) at approximately 30,800 \pm 14,300
     binding sites per platelet. AL-B inhibited the binding of labeled bovine
     von Willebrand factor (vWF) to platelets. Monoclonal antibodies
     against the 45-kDa N-terminal domain of platelet glycoprotein Ib inhibited
     the binding both of AL-B and of bovine vWF to platelets, and also
     inhibited platelet agglutination induced by AL-B and bovine vWF.
     Specific removal of the N-terminal domain of GPIb by treatment of the
     platelets with elastase or Serratia marcescens protease reduced
     the binding of labeled AL-B and bovine vWF to platelets and blocked
     platelet agglutination caused by both agonists. Monoclonal
     antibodies to glycoprotein IIb/IIIa, to bovine vWF, and to
     bovine serum albumin did not show any effect
     on the binding of AL-B to platelets. Our results indicate that the
     binding domain for AL-B on platelet GPIb is close to or identical with the
     one for vWF. This new protein may be a very useful tool for studying the
     interaction between platelets and vWF.

     The effect of peptic degradation on the immunological and antigenic
AB
     properties of bovine serum albumin (BSA) was investigated.
     Molecular fragments obtained after various times of digestion
     (3-360 min) were studied. Enzymatic digestion resulted in a rapid loss of
     serologically defined antigenic determinants. The immunogenicity of the
     fragments as measured by the level of reaginic and total anti
     BSA antibody response in BDF1 mice was also diminished.
     Pre-treatment of mice with fragments exhibiting a low density of
     B-cell interacting determinants before immunization with BSA,
     resulted in significant suppression of both the primary and secondary
     antibody response. The most effective immunosuppressive
     fragments were obtained following removal of peptides which bound
     to anti BSA antibodies. It was concluded that
     separate determinants on the BSA molecule were responsible for
     the immunogenic and suppressive properties of the antigen.

     The immunogenic properties of a peptic fragment of BSA
AB
     [bovine serum albumin] were investigated. BSA was subjected to
     limited proteolysis by pepsin and the resulting
     fragments were separated on DEAE cellulose. The fragment
     under consideration, fraction Ia (MW 8000-10,000), did not precipitate
     with anti-BSA serum but did inhibit the binding of specific
     antibody to labeled BSA, indicating the presence of
     determinants found on the native antiqen. BDF1 mice immunized with
     fraction Ia in Al (OH)3 gel or in complete Freund's adjuvant produced no
     significant antibody response as measured by passive cutaneous
     anaphylaxis (PCA) or by a modified Farr assay. The fragment
     elicited a PCA reaction in mouse skin sensitized with anti-BSA
            Treatment of mice with single doses of fraction Ia at various time
     intervals before immunization with BSA resulted in significant
     suppression of the formation of anti-BSA antibody.
     The conditions of suppression of the Ig[immunoglobulin]E response by the
     peptic fragment were studied in greater detail. Such
     suppression probably can be attributed to the presence of specific T
     [thymus-derived] suppressor cells.

ANSWER 6 OF 11 EMBASE COPYRIGHT (c) 2006 Elsevier B.V. All rights reserved on STN AN 80097580 EMBASE DN 1980097580 Immunological properties of peptic fragments of bovine serum ΤI albumin. Dosa S.; Pesce A.J.; Ford D.J.; et al. ΑU Dept. Med., Univ. Cincinnati Coll. Med., Cincinnati, Ohio, United States CS Immunology, (1979) Vol. 38, No. 3, pp. 509-517. . SO CODEN: IMMUAM CY United Kingdom DT Journal FS 026 Immunology, Serology and Transplantation LA English ED Entered STN: 9 Dec 1991 Last Updated on STN: 9 Dec 1991 The effect of peptic degradation on the immunological and antigenic AR properties of bovine serum albumin (BSA) was investigated. Molecular fragments obtained after various times of digestion (3-360 min) were studied. Enzymatic digestion resulted in a rapid loss of serologically defined antigenic determinants. The immunogenicity of the fragments as measured by the level of reaginic and total anti BSA antibody response in BDF1 mice was also diminished. Pre-treatment of mice with fragments exhibiting a low density of B-cell interacting determinants before immunization with BSA, resulted in significant suppression of both the primary and secondary antibody response. The most effective immunosuppressive fragments were obtained following removal of peptides which bound to anti BSA antibodies. It was concluded that separate determinants on the BSA molecule were responsible for the immunogenic and suppressive properties of the antigen. Medical Descriptors: *immune response immunogenicity immunosuppressive treatment mouse cattle Drug Descriptors: *epitope *bovine serum albumin *pepsin a (pepsin a) 9001-75-6 RN
